1 GENERAL DESCRIPTION

The ST77903 is a single-chip controller/driver for 16.7M-color, graphic type TFT-LCD. The 400-channel source driver has true 8-bit resolution, which generates 64 Gamma-corrected values by an internal D/A converter. The ST77903 is capable of connecting directly to an external microprocessor, and provides QSPI interface. In addition, because of the integrated power supply circuit necessary to drive liquid crystal; it is possible to make a display system with fewest components.

7.4. Quad-SPI Interface

Pin Name	Description
SCKP	Clock signal (Max=50MHz)
DA0	Serial input data lane 0
DA1	Serial input data lane 1
DA2	Serial input data data lane 2
DA3	Serial input data lane 3

Write command mode

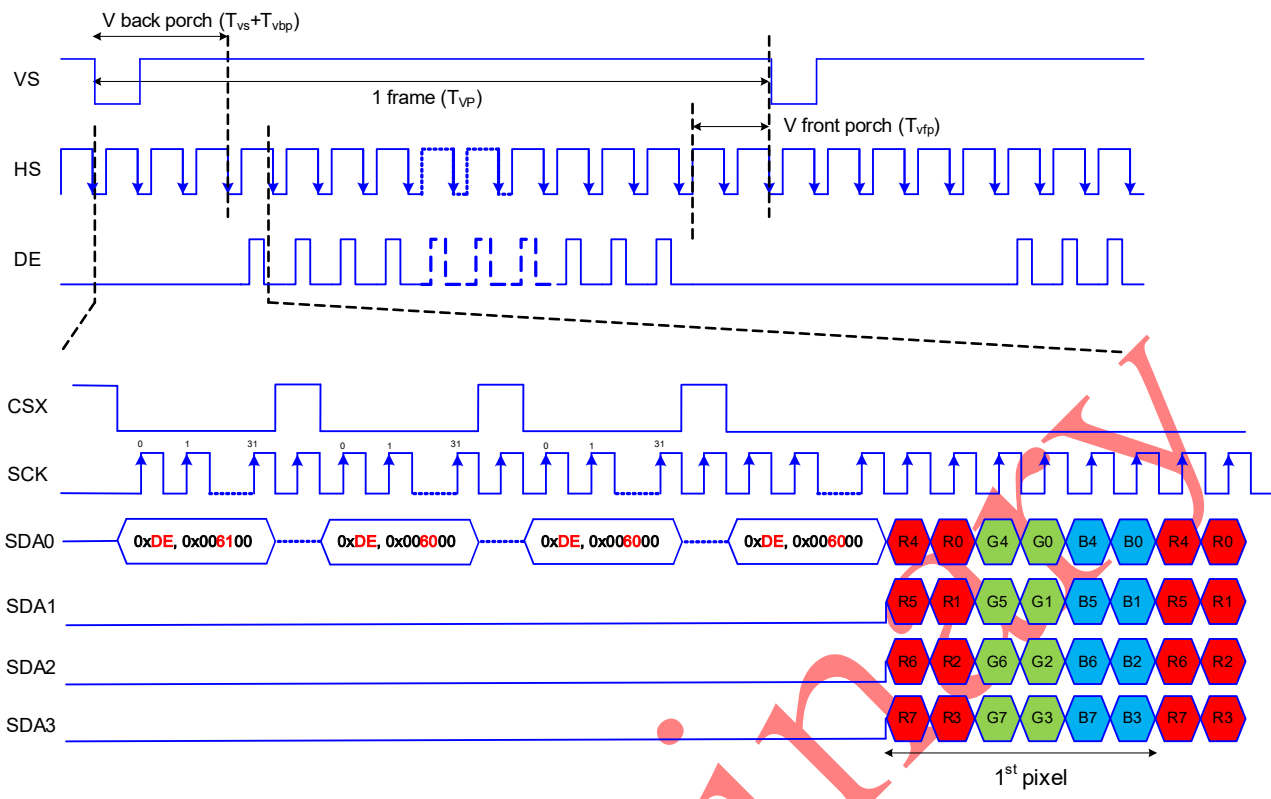

When host writes commands or parameter to ST77903, host needs to send 1 byte of write command instruction (0xDE). Then host sends 3 bytes of AD[23:0] which is composed of 1 byte of 0x00, 1 byte of command address and 1 byte of 0x00. After host sending instruction and AD[23:0], the following data is parameter (are parameters). When the last bit of parameter has been sent, CSX pin should be returned "H" level.

Write pixel data

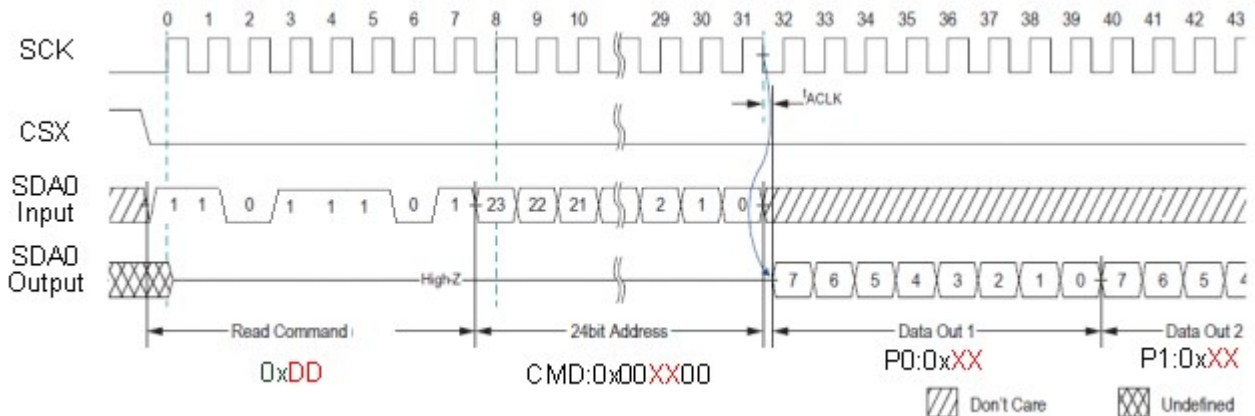

In write pixel data mode, the host sends one byte of instruction, 3 byte of AD[23:0] and pixel data. The instruction is transferred only by one lane of DA0, and data can be transferred 4 DA lanes.

The 0xDE+0x006100 must be issued at the beginning of each frame. The 0xDE+0x006000 must be issued at the beginning of each line.

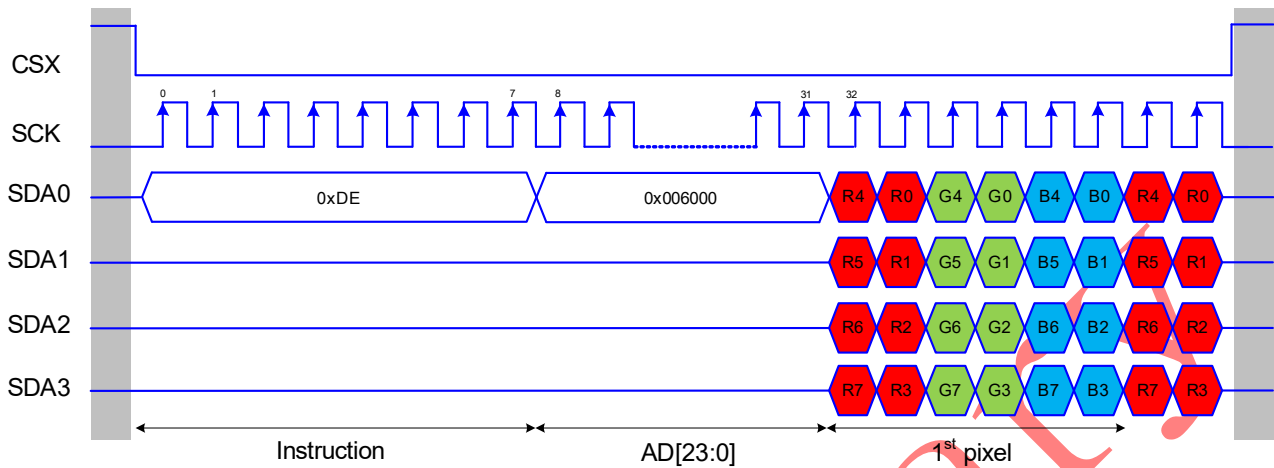

Read command mode

When host reads commands or parameter to ST77903, host needs to send 1 byte of write command instruction (0xDD). Then host sends 3 bytes of AD[23:0] which is composed of 1 byte of 0x00, 1 byte of command address and 1 byte of 0x00. After host sending read command and AD[23:0], the following output data is command address parameter (are parameters). When the last bit of parameter has been output, CSX pin should be returned "H" level.

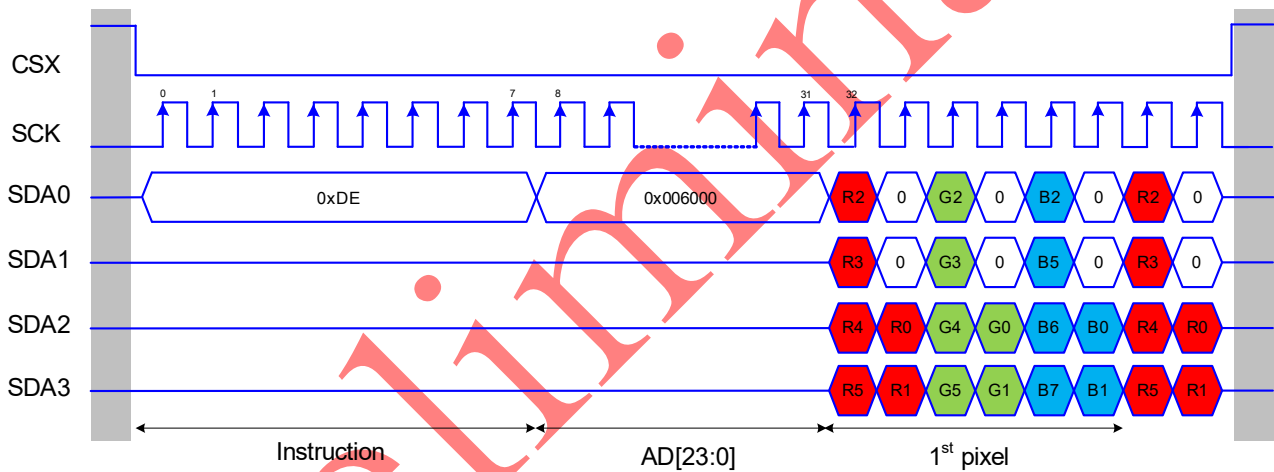

7.5. Color Format

QSPI RGB666

QSPI RGB565

7.6. RGB Interface

RGB Interface Selection

The color format selection of RGB Interface for ST77903 is selected by setting the IM and command 3Ah, DB [7:0].

IM	3Ah	RGB Interface Mode	Data pins
1,0	101	3-SPI with RGB565	DB[7:2]
1,0	110	3-SPI with RGB666	DB[7:2]
1,0	111	3-SPI with RGB888	DB[7:0]
1,1	101	4-SPI with RGB565	DB[7:2]
1,1	110	4-SPI with RGB666	DB[7:2]
1,1	111	4-SPI with RGB888	DB[7:0]

RGB Color Format

ST77903 supports two kinds of RGB interface, DE mode and HV mode, and only 6bit data format. When DE mode is selected and the VSYNC, HSYNC, DOTCLK, DE, D [7:0] pins can be used; when HV mode is selected and the VSYNC, HSYNC, DOTCLK, D [7:0] pins can be used. When using RGB interface, only serial interface can be selected.

Preliminary

RGB Interface Definition

The display operation via the RGB interface is synchronized with the VSYNC, HSYNC, and DOTCLK signals. The data can be written only within the specified area with low power consumption by using window address function. The back porch and front porch are used to set the RGB interface timing.

Figure 3 DRAM Access Area by RGB Interface

Please refer to the following table for the setting limitation of RGB interface signals.

6bit RGB interface:

Parameter	Symbol	Min.	Typ.	Max.	Unit
Horizontal Sync. Width	hpw	TBD	TBD	TBD	Clock
Horizontal Sync. Back Porch	hbp	TBD	TBD		Clock
Horizontal Sync. Front Porch	hfp	TBD	TBD	TBD	Clock
Vertical Sync. Width	vs	TBD	TBD	TBD	Line
Vertical Sync. Back Porch	vbp	TBD	TBD		Line
Vertical Sync. Front Porch	vfp	TBD	TBD	TBD	Line

Note:

Typical value are related to the setting of dot clock is 17MHz and frame rate is 60Hz..

In with ram mode, $hpw+hbp+hfp \geq 66$

In without ram mode, $hpw+hbp \geq 60$

RGB Interface Timing

The timing chart of RGB interface DE mode is shown as follows.

Note: The setting of front porch and back porch in host must match that in IC as this mode.

Figure 4 Timing Chart of Signals in RGB Interface DE Mode

The timing chart of RGB interface HV mode is shown as follows.

Figure 5 Timing chart of RGB interface HV mod

VSYNC, HSYNC, and DOTCLK signals must be supplied during a display operation period.

In RGB interface mode, the panel controlling signals are generated from DOTCLK, not the internal clock generated from the internal oscillator.

In RGB interface mode, each of RGB dots are transferred in synchronization with DOTCLK signals. In other words, one pixel data needs to take three DOTCLKs to transfer.

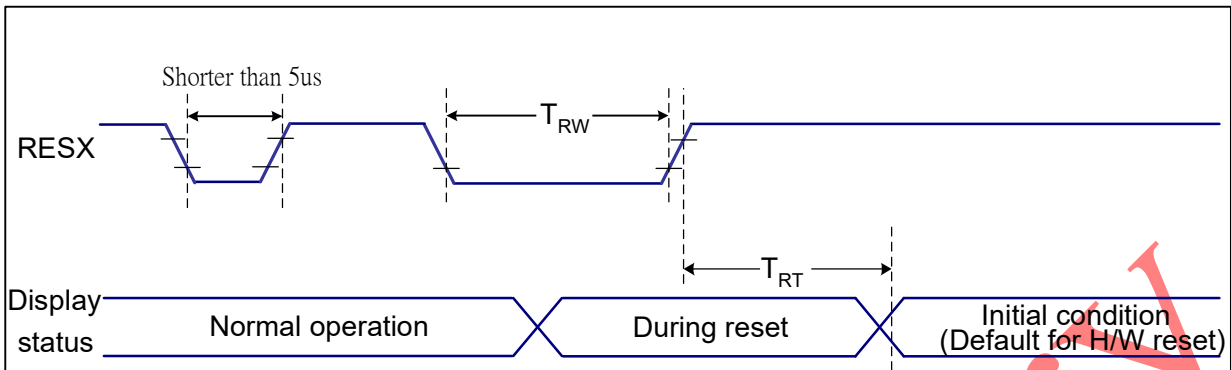

In RGB interface mode, the cycles of VSYNC, HSYNC, ENABLE, DOTCLK signals must be set correctly so that the data transfer is completed in units of pixels.

When switching between the internal operation mode and the external display interface operation mode, follow the sequences below in setting instruction.

In RGB interface mode, the front porch period continues until the next VSYNC input is detected after drawing one frame.

In RGB interface mode, a RAM address is set in the address counter every frame on the falling edge of VSYNC.

7.7. Reset Timing

VDDI=1.8V, VCI=2.8V, AGND=DGND=AGNDR=0V, $T_a=25^\circ\text{C}$

Related Pins	Symbol	Parameter	MIN	MAX	Unit
RESX	TRW	Reset pulse duration	10	-	us
	TRT	Reset cancel	-	5 (Note 1, 5)	ms
			-	120 (Note 1, 6, 7)	ms

Notes:

- The reset cancel includes also required time for loading ID bytes, VCOM setting and other settings from NVM (or similar device) to registers. This loading is done every time when there is HW reset cancel time (t_{RT}) within 5 ms after a rising edge of RESX.
- Spike due to an electrostatic discharge on RESX line does not cause irregular system reset according to the table below:

RESX Pulse	Action
Shorter than 5us	Reset Rejected
Longer than 9us	Reset
Between 5us and 9us	Reset starts

- During the Resetting period, the display will be blanked (The display is entering blanking sequence, which maximum time is 120 ms, when Reset Starts in Sleep Out –mode. The display remains the blank state in Sleep In –mode.) and then return to Default condition for Hardware Reset.
- Spike Rejection also applies during a valid reset pulse as shown below:

5. When Reset applied during Sleep In Mode.
6. When Reset applied during Sleep Out Mode.
7. It is necessary to wait 5msec after releasing RESX before sending commands. Also Sleep Out command cannot be sent for 120msec.

Preliminary

7.8. Power ON/OFF Sequence

VDDI and VCI can be applied in any order.

VCI and VDDI can be power down in any order.

During power off, if LCD is in the Sleep Out mode, VCI and VDDI must be powered down minimum 120msec after RESX has been released.

During power off, if LCD is in the Sleep In mode, VDDI or VCI can be powered down minimum 0msec after RESX has been released.

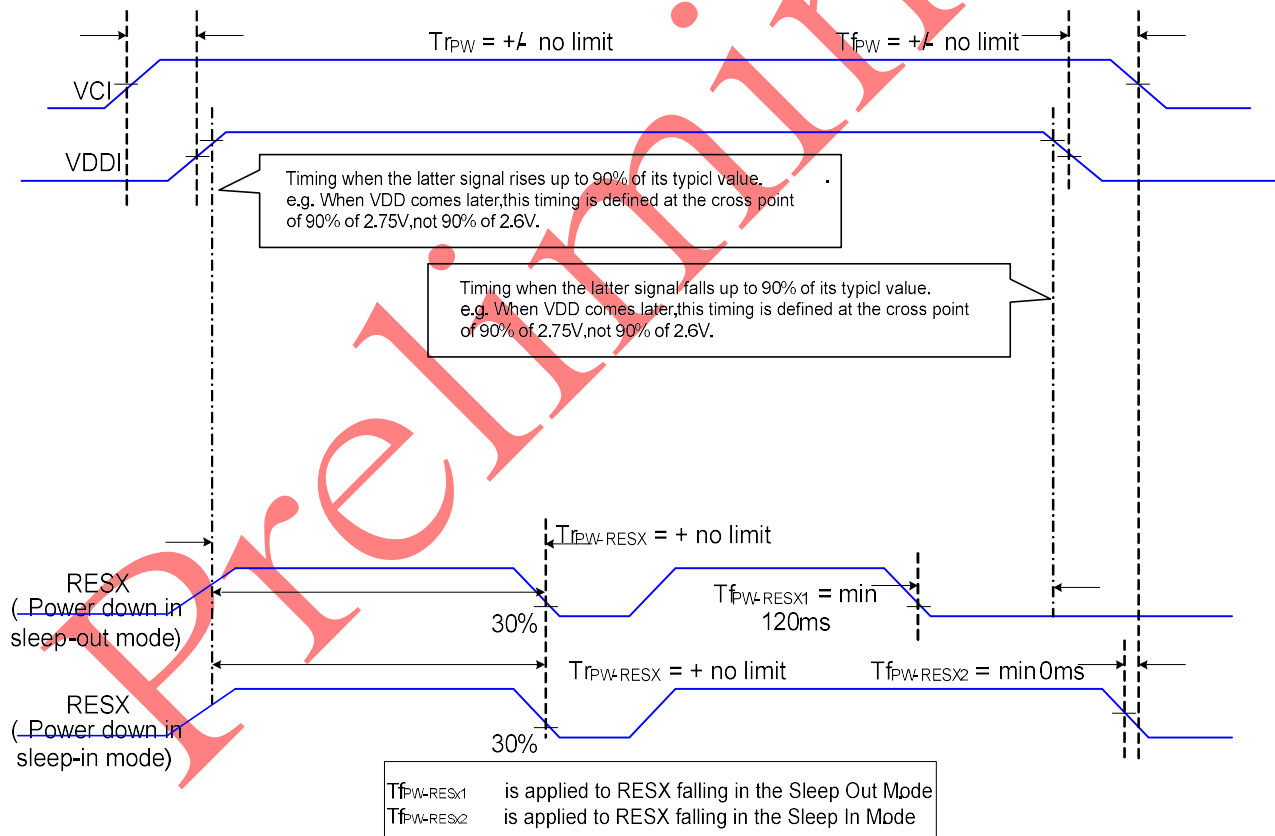

Note 1: There will be no damage to the display module if the power sequences are not met.

Note 2: There will be no abnormal visible effects on the display panel during the Power On/Off Sequences.

Note 3: There will be no abnormal visible effects on the display between end of Power On Sequence and before receiving Sleep Out command. Also between receiving Sleep In command and Power Off Sequence.

Note 4: If RESX line is not held stable by host during Power On Sequence as defined in the sequence below, then it will be necessary to apply a Hardware Reset (RESX) after Host Power On Sequence is complete to ensure correct operation. Otherwise function is not guaranteed.

The power on/off sequence is illustrated below

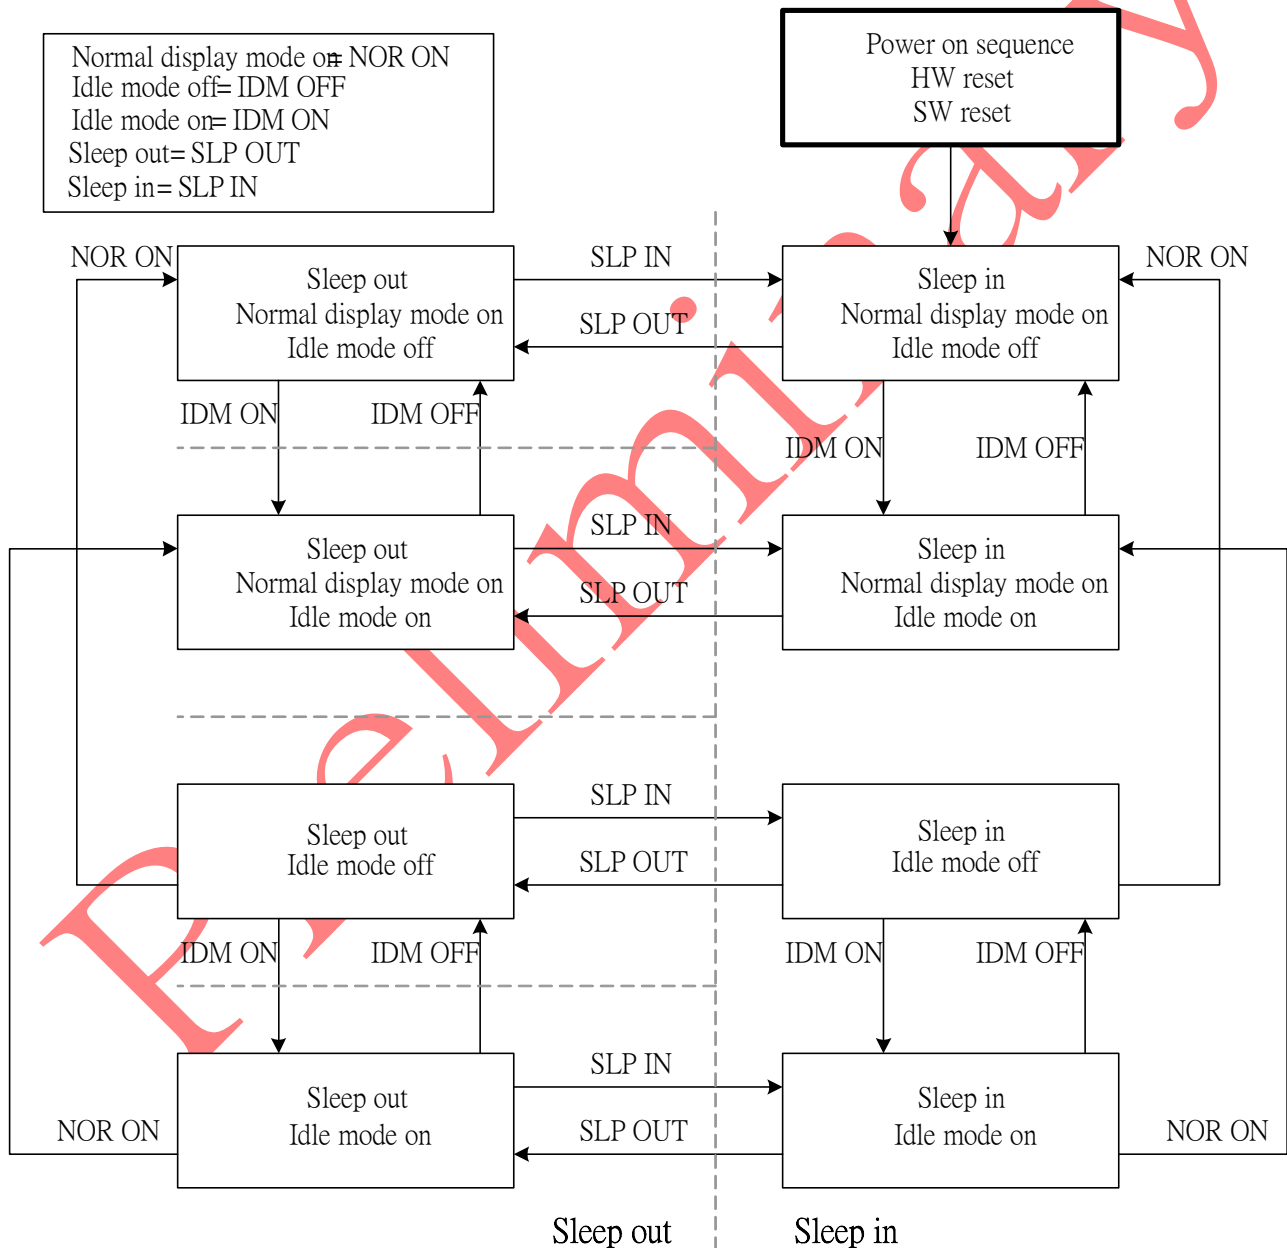

7.9. Uncontrolled Power OFF

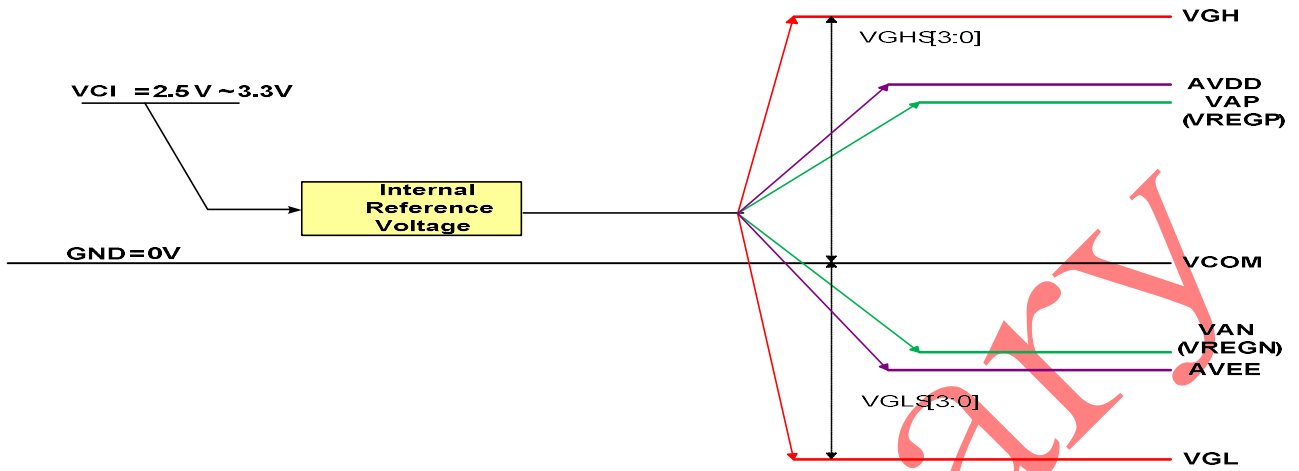

The uncontrolled power-off means a situation which removed a battery without the controlled power off sequence. It will neither damage the module or the host interface.

If uncontrolled power-off happened, the display will go blank and there will not any visible effect on the display (blank display) and remains blank until "Power On Sequence" powers it up.

8. FUNCTION DESCRIPTION

8.1. Tearing Effect

The Tearing Effect output line supplies to the MPU a Panel synchronization signal. This signal can be enabled or disabled by the Tearing Effect Line Off & On commands. The mode of the Tearing Effect signal is defined by the parameter of the Tearing Effect Line On command. The signal can be used by the MPU to synchronize Frame Memory Writing when displaying video images.

10.1.1 Tearing effect line modes

Mode 1, the Tearing Effect Output signal consists of V-Blanking Information only:

tvdh= The LCD display is not updated from the Frame Memory

tvdl= The LCD display is updated from the Frame Memory (except Invisible Line – see above)

Mode 2, the Tearing Effect Output signal consists of V-Blanking and H-Blanking Information, there is one V-sync and 480 H-sync pulses per field.

thdh= The LCD display is not updated from the Frame Memory

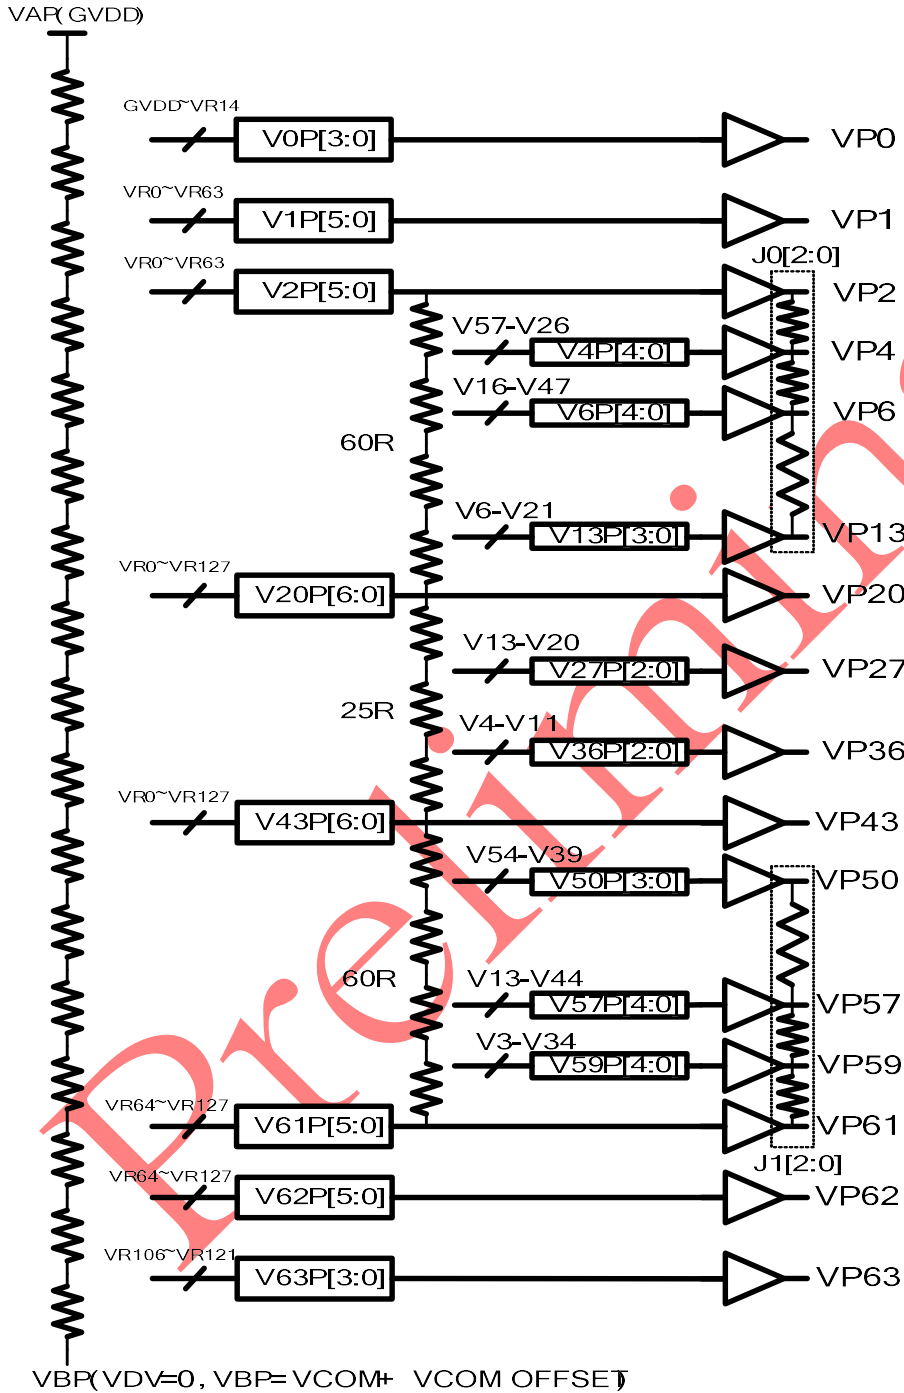

thdl= The LCD display is updated from the Frame Memory (except Invisible Line – see above)

Note: During Sleep In Mode, the Tearing Output Pin is active Low.

8.2. Gamma Correction

ST77903 incorporate the gamma correction function to display 16.7M colors for the LCD panel. The gamma correction is performed with 3 groups of registers, which are gradient adjustment, contrast adjustment and fine- adjustment registers for positive and negative polarities.

Description	<p>-This command turns on the display module's Tearing Effect output signal on the TE signal line when the display module reaches line N. The TE signal is not affected by changing MV.</p> <p>-The tearing effect line on has one parameter that describes the tearing effect output line mode.</p> <p>-The tearing effect output line consist of V-blanking information only.</p> <p>Note that set tear scanline with N=0 is equivalent to tearing effect line on with TEM=0.</p> <p>The tearing effect output line shall be active low when the display module is in sleep mode</p>												
Restriction	<p>This command takes affect on the frame following the current frame. Therefore, if the tear effect (TE) output is already on, the TE output shall continue to operate as programmed by the previous tearing effect line on or set tear scanline command until the end of the frame</p>
